A01 Reflection

During this lab session, I worked through the full process of setting up GitHub, exploring its features, and creating my first Jupyter Notebook using an online environment. I began by creating a GitHub account and taking time to understand the layout of the dashboard. This included learning how repositories are organized and how issues and pull requests fit into the workflow of version control. After getting comfortable with the interface, I created a new repository named jupyter-exploration and initialized it with a README file. I edited the README to include a short description of the lab session and committed the changes directly to the main branch, which gave me my first hands-on experience with making a commit.

For the Jupyter Notebook portion of the lab, I chose to use Google Colab instead of installing Jupyter locally. I signed in with my Google account and created a new notebook. Inside the notebook, I added a Markdown cell and wrote a simple message to test the formatting. Then I added a code cell and wrote a basic Python command, `print("Hello, World!")`, and ran the cell to see the output. This helped me understand how Jupyter mixes text and code in a single interactive environment. After finishing the notebook, I saved it and downloaded the .ipynb file to my computer. To get the notebook to GitHub, I uploaded the file.

Throughout this lab, I learned how GitHub supports version control by tracking changes and organizing projects through repositories. I gained a better understanding of how commits

work and how GitHub Desktop connects the online repository with the files stored on my computer. Working with Jupyter Notebook taught me how useful it is for writing and running code in small, testable pieces while also allowing explanations and notes through Markdown. Using Google Colab made the process easier because I did not have to install anything, and I could start working immediately.

One challenge I faced was figuring out how to upload the notebook to GitHub. At first, I was unsure how to move the file into the repository, but once I installed GitHub Desktop and saw how cloning and pushing worked, the process became much clearer. Understanding how the local folder and the online repository stay connected helped me feel more confident using version control tools.

In conclusion, this lab gave me practical experience with two important tools: GitHub for managing and sharing code, and Jupyter Notebook for interactive computing. I feel more comfortable navigating both platforms and can see how they will be useful in future assignments and projects. I would like to continue practicing GitHub workflows such as branching and merging, and I am also interested in exploring more advanced Jupyter features like installing packages, using different kernels, and working with datasets. The lab was helpful and straightforward, and using an online notebook environment made the learning process smooth and accessible.
